Overview & Purpose

Project : Database management system for movie reviews and ratings

Movies are one of the most essential and well-liked forms of entertainment nowadays. It can be challenging to find decent movies or movies that appeal to one's taste with their hectic schedule and extensive movie library. I want to build a website to address this issue and make people's hectic lives a little simpler.

In this website, people can create an account. They can search for movies, give reviews on movies and see other people's reviews also. Movies will get ratings based on these reviews.

Users can watch the trailers of the movies. They can also create a watch list based on their taste.

Admins will add new movies and their trailers to the existing database.

Objectives

- Develop a user-friendly movie website to provide information and engage movie enthusiasts.
- Display a collection of movies, including details such as title, synopsis, and ratings.
- Enable users to search and filter movies based on genre, actors, or release dates.
- Allow users to create accounts, save favorite movies in their watchlist, and leave ratings or reviews.
- Ensure a responsive design for seamless user experience across devices.
- Implement a secure user authentication system for account protection.
- Admin panel for efficient movie management and content updates.

Project Design

The project did not go as I initially planned.

In our movie review website project, we aim to incorporate **two** distinct user roles within our database management system (DBMS).

The first user type consists of **end users** who will have personalized accounts to store their information, such as movie **watchlists**, etc. These users will have the ability to browse through a diverse catalog of movies, submit **reviews**, and manage their personal **lists** by **adding**, **updating**, and **removing** movies at their convenience.

Each customer will have exclusive access to their own **personalized** watchlists, granting them full control over their content.

The second user type is the **admin**. Admins will have access to a dedicated and user-friendly admin dashboard, allowing them to directly manage the database. Each admin will have a unique **username** and **password** associated with their account, granting them the authority to **modify**, **delete**, and **add** movie listings based on availability and updates.

It's important to emphasize that admins **do not** have access to user information. The admin dashboard ensures a strict separation between admins and users, ensuring the confidentiality and security of customer data. Admins will solely focus on maintaining the database and overseeing the content.

Project Workflow

The project's initial planning is as follows:

- Building Login and Signup Page
- Creating the landing page whilst building the central dark theme of the store.
- Creating the Database based on the Relational Database Model.
- Connecting the Database to the Front-End and letting users to sign in and create accounts.
- Creating the rest of the pages as follows.
- Building the watchlist system and connecting the database efficiently.

Resources

HTML

All the elements were added using simple HTML tags. We used nothing special to do what we did.

CSS

I exclusively utilized CSS to style the entire website. This involved implementing CSS for animations on the login/signup page, designing color combinations, and formatting text and buttons. I extensively explored YouTube to gather knowledge and skillfully applied it to produce an impressive outcome. The primary hurdle I faced was crafting a cohesive dark theme that seamlessly translated across all the pages, and subsequently adapting all the pages to align with this dark theme.

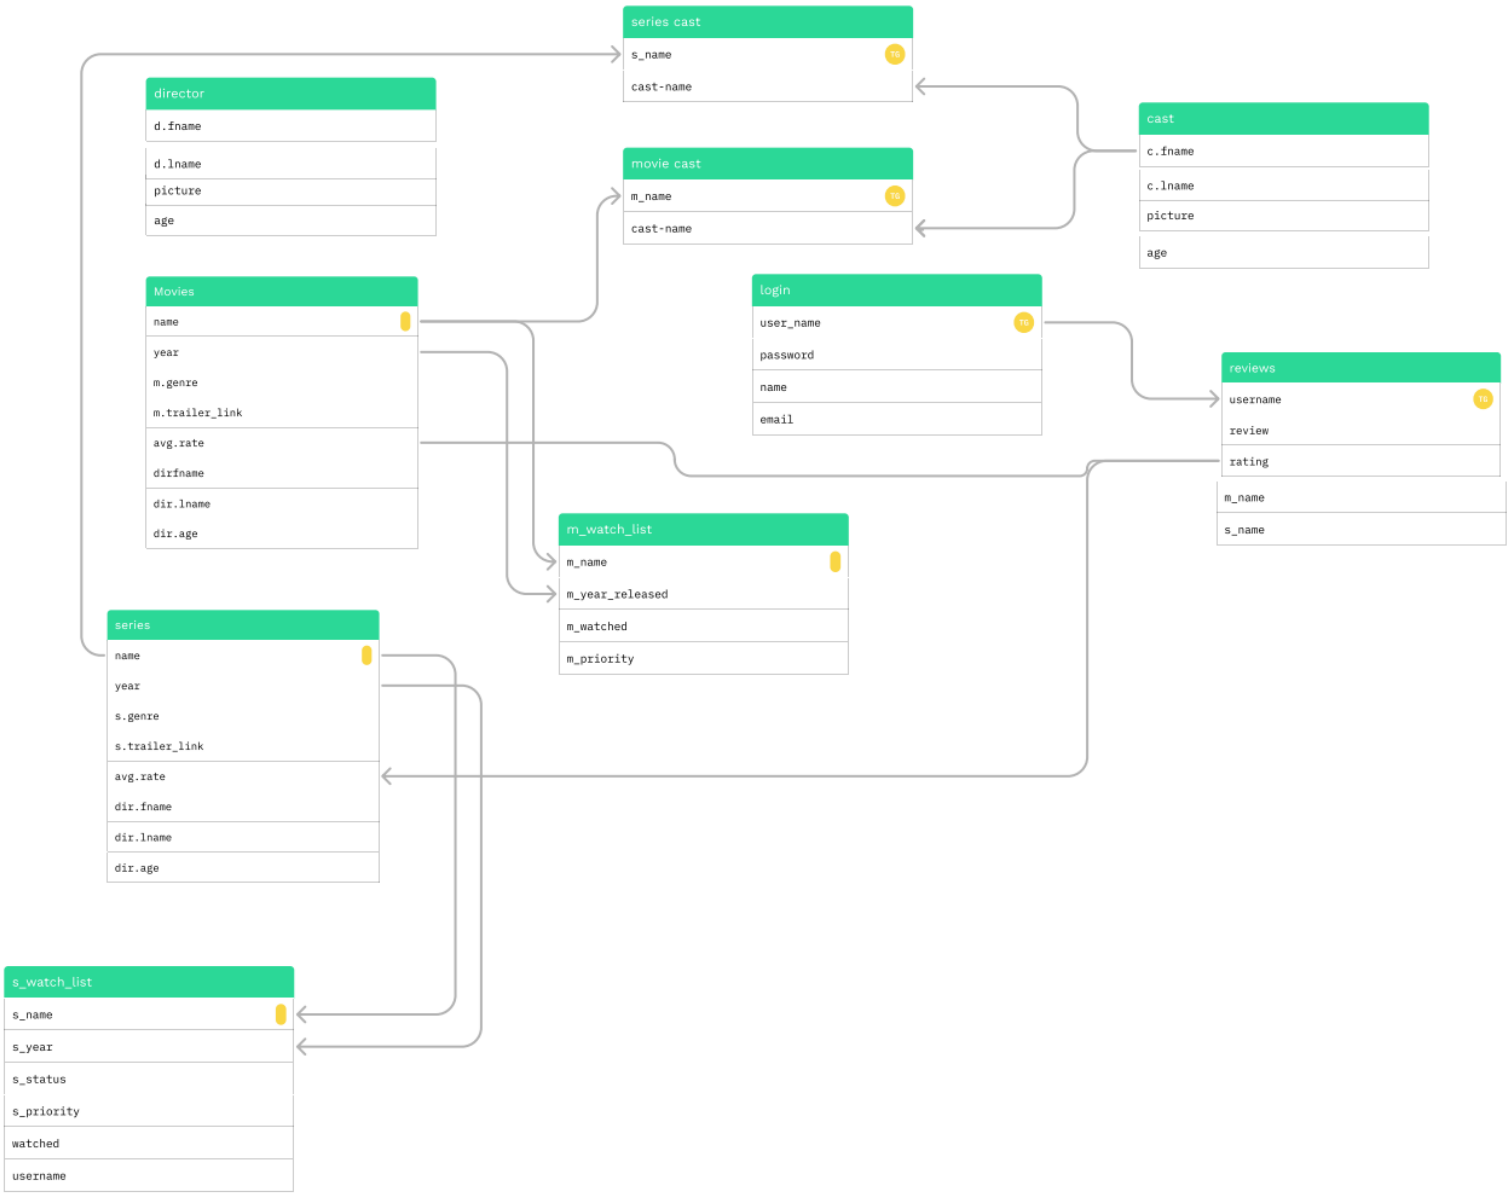

Javascript

I used Javascript only in the login and signup page to employ the animations.

PHP

PHP served as the backbone of our project, handling the backend operations. Through PHP, we established seamless connections with the database and efficiently stored user information by leveraging its simplicity and effectiveness.

Schema Diagram

Discussion

Remarks

I initially tried to complete the project satisfactorily with all the functionalities I initially planned. However, I could not implement many of the functions such as the watchlist which seems like a huge failure to me.

Nevertheless, I successfully implemented the login and signup system. Users can sign up using their email address and a unique username. They can login to their account anytime and edit/update their personal details or delete their account.

I managed to make the website look really nice since I really like doing front end work. However, I fell short with the backend.

Last but not least, I learnt a lot from this project. I learnt to solve problems on my own and learnt a great deal about front end development.

I hope you like what I accomplished with this project.
